Most existing Virtual Patients utilize simplistic, predictable, and prescriptive approaches that limit deductive learning and the development of decision-making skills for medical students. We have designed a chat-based virtual patient for performing patient interviews, physical examinations, and investigations to help medical students develop reasoning skills. In this paper, we present results from a two-part study. In the first part, we conducted a usability evaluation with seven medical students and six clinicians. The objectives of the usability evaluation was to determine how VIP’s user interface and its features affect the usability (efficiency, effectiveness and learnability) as well as the general subjective user experience associated with the use of system. Each participant completed a user experience, system usability scale, and a self-prepared survey form. A significant difference was seen between the results of students and tutors. Due to a lack of training data, the chatbot model predicted incorrect responses that led participants to feel frustrated. In the second part of study, we have retrained the chatbot model using the feedback and designed an error correction approach and engaged seven new medical students to test the chatbot intensively — a total of 2169 user interactions were performed with the chatbot. Of that, 77.4% were properly answered by the bot, 10.8% were out-of-domain concepts, 8.6% were unknown concepts (Li et al., 2018), 3.3% were corrected using the error correction approach designed.

Keywords: virtual patient, medical education, usability evaluation

INTRODUCTION

A large percentage, 41-60% of medical graduates, feel clinically unprepared after university graduation (Cave et al., 2007; Goldacre et al., 2003; Ochsmann et al., 2011) due to the decreasing access of students to real patients. Training is designed based on a back-to-front approach where the student learns about the disease by analysing a diagnosed patient. There are relatively limited opportunities for the students to practice engaging with a patient, using a more natural perspective approach, beginning with a symptom, and concluding with diagnosis and management. Currently, medical schools use both mannequin-based and standardized patient simulation to overcome these limitations. However, the limitations of these approaches are that they can only involve a small number of students at one time, and the faculty have to conduct repeated sessions to cater to the cohort.

In the past two decades, medical education has placed increased reliance on simulation technologies, such as virtual patient (VP) simulations, to boost the growth of learner knowledge and to shape the acquisition of clinical skills for medical students and health professionals (Barry Issenberg et al., 2005). Most of the VPs have, however, been narrative based, using a linear or menu-driven model with preselected options, which are relatively simplistic, predictable, and prescriptive in their approaches limiting the opportunities of the student to engage the virtual patient in a more naturalistic way, to practice his/her decision-making skills. We have designed a virtual patient platform that allows a more natural and realistic way of interaction between students and the virtual integrated patient model. We believe that a well-designed VP, one that is easy and intuitive to use, will help students to remain engaged with exploratory learning, and eventually improve disease understanding and clinical reasoning skills. Therefore, a user-centred approach has been adopted for the development of the VP to ensure that the system is easy and enjoyable to use and meets the pedagogical goals. The system will be subjected to iterative user testing, evaluation and improvement design throughout the development lifecycle. This paper details the first user testing and a study conducted to improve the model performance.

In the next section, we introduce an overview of the design of the virtual integrated patient. Subsequently, the design of the usability study. In section 4, the results of the user study will be discussed. Following which, there
would be a brief overview of an improvement study that was conducted to improve the system further. Through thorough exercises, the system learned a variety of new questions from experienced medical students.

**DESIGN OF VIRTUAL INTEGRATED PATIENT**

Virtual Integrated Patient (VIP), generates realistic virtual patients which students can interact with using a free-text interface, through the process of interviewing (Figure 1), conducting a physical examination (e.g., to check the temperature, blood pressure, heart rate) and order of investigations (e.g., full blood count, x-ray, MRI, etc.). The patients generated are realistic because they come with randomly generated, rich and comprehensive case details, such as gender, age, ethnicity, presenting symptoms, family, social and medical history, drug history, travel history, and genetics. The engagements allow medical students to prospectively move from presenting symptom to eventual diagnosis, thus allowing the development of clinical reasoning skills.

**Figure 1. Student performing an interview with a virtual patient**

In clinical practice, clinicians are trained to inform the patients or seek consent from the patients before they perform a physical examination or send patients for investigations. Similarly, on the VIP, students are reminded that they can only get access to perform a physical exam or to order investigations when they have informed the patient or have sought consent from the patient, as described in Figure 2.

**Figure 2. Taking patient consent to perform physical examination and investigation**

The participant subsequently will be allowed to navigate to an examination interface by clicking on the link shown in the patient response within the chatbot. In the examination module, the participant clicks on any part of the human anatomical figure and types in the specific examination they wish to perform. As demonstrated in Figure 3, to check the patient temperature, participants have to input “temperature”. Similarly, to order an investigation, the participant has to inform the patient or seek consent from the patient before they input the specific investigation name.
Currently, the VIP provides feedback for the cost incurred to the patient based on investigations ordered and efficiency of the student’s engagement with the VIP. The latter is calculated based on the number of interview questions asked, examinations, and investigations negotiated before a diagnosis is made. The norms for these assessments are empirically made at the moment but can be better calibrated as more data is harvested according to the seniority of the student. Clinicians are trained to start the interview by greeting the patient, verifying patient name, identity, and encouraged to ask for the patients’ consent while asking any sensitive or personal information. The participant is assigned a penalty if they ignore any of these steps and rewarded for compliance. When the participant is ready to make a diagnosis, they simply indicate by clicking *Ready to Diagnose* button (Figure 1) and asked to re-enter brief case notes from the patient interview, physical examination, and investigations. They are then able to make a diagnosis and prescribe a treatment plan for the patient. Subsequently, the patient’s actual diagnosis and treatment will be shown for the student to do personal reflection and review.

**USABILITY EVALUATION**

**AIM OF USABILITY EVALUATION**

Usability is defined as “the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use” (ISO 9241-11:2018). The objectives of the usability evaluation was to determine how VIP’S’s user interface and its features affect the usability (efficiency, effectiveness and learnability) as well as the general subjective user experience associated with the use of system.

This was achieved through a user-based evaluation, where the usability and user experience were evaluated using targeted end users of the system, which in this case were medical students. The study also aimed to seek feedback from clinicians (tutors) on the usefulness of the VIP platform as a tool for teaching and training for clinical reasoning skills.

**PARTICIPANTS DEMOGRAPHICS**

In Phase 1, a total of 13 participants (seven medical students and six clinicians) were recruited to evaluate the usability of VIP. All of them were Singapore citizens, and majority were Chinese (12/13). Eight out of 13 participants were male. Of 7 students, 6 were the second-year medical students, and one was a fourth-year medical student, and their ages ranged from 20 to 23 with an average age of 21. Of 6 clinicians, their ages ranged from 40 to 52 years old, with an average age of 46.5 years old, and their clinical working experience ranged from 15 to 27 years. All the participants are informed to sign a consent form before starting the study. There was an omission of a 4th-year participant during analysis to make a precise comparison between only second-year students and clinicians.

**PROTOCOL**

Each participant had to complete two patient cases that covered interviewing patient, examining, and ordering lab investigations. The participants were briefed on the aim of the study and viewed the tutorial before starting. Guided...
by the facilitator, participants were asked to think aloud while performing the tasks - what they are trying to achieve, how they think they will achieve them, unexpected systems responses, i.e. if something happened which they did not expect or if something they were expecting to happen did not happen. Each participant’s interaction with the VIP were logged and video recorded. Thereafter, participants completed a user experience questionnaire, system usability scale, and a self-developed questionnaire. A semi-structured interview was conducted to follow-up on the observations during task performance (such as difficulties encountered, expressions of frustrations, etc) and capturing all participants’ subjective feedback on the VIP system.

**USER EXPERIENCE QUESTIONNAIRE**

The User Experience Questionnaire (UEQ) contains 6 scales (e.g., attractiveness, perspicuity, efficiency, dependability, stimulation, and novelty) with 26 items. The attractiveness scale has 6 items, and all other scales have 4 items. Each item is scaled from -3 to +3. Thus, -3 represents the most negative answer, 0 a neutral answer, and +3 the most positive answer (Schrepp, 2017).

**SYSTEM USABILITY SCALE**

The System Usability Scale (SUS) consists of 10 items to examine “usability” and “learnability” of a product. All items are measured on a 1 to 5 (1–Strongly disagree, 5–Strongly agree). Calculation of the SUS score is achieved by converting the 1 to 5 scale to a 0 to 4 scale. For items 1,3,5,7 and 9, the score contribution is the scale position minus 1. For item 2,4,6,8 and 10, the contribution is 5 minus the scale position. The overall SUS value is calculated by multiplying the sum of the scores by 2.5 (Brooke, 1996). Thus, the total score ranged from 0 to 100.

**SELF DEVELOPED QUESTIONNAIRE**

The self-developed questionnaire includes 15 questions to score patient responses, labels on menu items, and popup boxes, consistency of icons, colours used, navigation, organization of items, performance metrics, physical examination and placeholders in input boxes. All questions are measured on a 1–5 scale (1–Strongly disagree, 5–Strongly agree).

**RESULTS**

In the UEQ, students rated all items positively and the mean score of each item ranged from 0.29 to 2.29, with especially high mean scores (≥ 2.00) on items of enjoyable, valuable, interesting, good, practical and meet expectations. The students rated the low mean scores (< 1.00) on predictable, fast, and leading-edge. The scores of all items were rated lower in clinicians than students. The clinicians rated more negatively on some items, namely fast-slow (-1.33), pleasing-unlikable (-0.67), efficient-inefficient (-1.33) (Figure 4).

The mean scores of the scales of attractiveness, efficiency, and dependability were negative in clinicians (Figure 5). An Independent sample t-test between the students and clinicians showed that there were statistically significant differences in attractiveness, efficiency, perspicuity, dependability, and stimulation between them (p < 0.05) as shown in table 1 below.

In System Usability Scale (SUS), the mean score of each item ranged from 2.43 to 3.43 in students and 1.50 to 2.67 in clinicians. The students rated higher mean scores of all items than clinicians. When the comparison of the mean score of each item was performed, the students rated significantly higher scores on items of “I think that I would like to use this platform frequently”, “I found the platform unnecessarily complex”, “I thought the platform was easy to use”, and “I found the various functions in this platform were well-integrated” than those in clinicians. The mean score of total SUS score was 71.43 in students and 53.75 in clinicians, and there was a statistically significant difference in the total mean SUS score between students and clinicians (p < 0.05) as shown in Table 2.

Similar to the findings of the UEQ and SUS, the students rated higher scores on all 15 items than the clinicians in the self-developed questionnaire (Figure 7). An Independent t-test comparison between the students and the clinicians indicated that there was statistically significant difference in more than half of items (p < 0.05) as shown in Table 3.

The difference between the students’ and tutors’ usability score can be attributed to the differences in technical proficiency. Medical students comprise mainly of young adults who are more at-home with a chat-based interface, whereas the tutors are less familiar in engaging with online (virtual) patients. Medical students had more positive perceptions of the system as a learning tool and found the system to be engaging and simple to use. The tutors on the other hand found it less useful to them as they were trying to engage with the platform as a student. However, during the interview sessions, they conceded the system as a useful tool to support students’ learning.

**OBSERVATIONS FROM TASK PERFORMANCE AND FEEDBACK FROM SEMI-STRUCTURE INTERVIEW**

Most participants had positive experiences using the platform. One of their positive experiences was that they felt that VIP was a good, fun and an easy and interesting platform to use, even though it could be further improved. Quite a number of participants liked the format and layout of the platform as they felt that it was simple and clear to learn and use. Some participants thought that VIP was a good platform to practice history-taking in a safe online
environment without feeling stressed, as there were no limitations to the questions to be asked. Another positive experience, pointed out by one participant, was that the responses were quite practical and realistic. Thus, the participant felt that the platform was quite flexible. With the platform providing specific responses to each of the participants’ questions, participants liked how the programme released one information at a time and further information must be probed by the participants themselves. In addition, for the lab investigations, the participants liked how the programme gave realistic results displaying descriptions of the investigations. The cases seemed more personalised, rather than generic, to the participants.

Despite the positive experiences, some participants also expressed some negative experiences when using the platform. The default model was not able to answer open-ended, long sentence and follow-up questions. Some participants had the conception that the platform was intended to replace the simulated patient or real patient and stated that the interview section was unrealistic. They also complained that they often felt frustrated from the inaccurate responses.

We classified the errors encountered in 3 different categories: unknown concept, out-of-domain and context errors. If the intent of the question asked by the student is already defined in the chatbot model but not predicted correctly, then it is classified as an unknown concept. If the model was not aware of any input, then it is classified as an out-of-domain concept (Li et al., 2018), and if the patient’s response shown to the user doesn’t follow the context of the current state of the conversation, then it is classified as a context error. Analysing the student logs, we found that 49.7% of the questions were predicted correctly, 18.3% were unknown concepts, 30% of out-of-domain concepts and 2% of issues were due to context. Due to the missing data in the system, the computer cannot provide appropriate responses to the participants’ questions, which made the participants feel frustrated. A common issue also occurred when participants presented questions in different ways. In this case, although the system has the data relating to the question, the computer could not recognize the different presentations of the questions, which resulted in many unknown concepts. There were some mapping issues due to the context of the conversation and thus, the computer could not recognise the context questions or follow-up questions, which resulted in the generation of wrong answers.

In terms of interaction design, one of the major problems was navigating from history taking (interview) to physical examination. Participants were required to seek permission from the patients for physically examination in order for the system to move to the physical examination segment. However, most participants looked for a button to click to move to physical examination.

Another common problem encountered was most participants clicked on either the ear, forehead/face and mouth for the measurement of body temperature. However, the temperature was designed to be taken under the axilla. Participants found it difficult to navigate between the physical examination and the interview. When participants tried to order laboratory investigations, they also encountered some problems as there were some unregistered investigations in the system and also costing had an implementation problem where the system provided doubled costs when the student ordered the same investigation twice. Participants expressed their displeasure over some issues in the programme, such as the need to re-type or rewrite a brief of the patient case notes before diagnosing, as they found it tiring to cut and paste the words from the case notes.

REDESIGNING VIP

We have retrained the chatbot model using the usability study feedback. Following are few changes we have incorporated in the design.
1. Consider the student asked the patient How long you have fever? for which the platform is not been trained and so the program matched the response for the question How long? as it was similar and the patient responded as Since 3 days ago which is for the symptom cough the patient may be suffering from. To avoid these inconsistencies, we have tailored the response more specific to the question i.e., I got cough since 3 days ago.

Figure 8. Nearby list of questions given to correct unknown concepts

2. We have used nearby predictions made by the natural language understanding model to correct unknown concepts. Whenever a user asks a question in the chat, the question is detected using a trained language model. Rasa NLU (Rasa Documentation) has been used to deploy the chatbot language model. Rasa NLU predicts a list of intents, each associated with a confidence level. By default a intent with high confidence level is chosen and a patient response for that intent is shown to the user. For example, If the question asked is Did you take any panadol? which is focussing on patient medications, then the chatbot incorrectly predicts a intent named any tremors with an confidence level 0.97, medications intake with an confidence level 0.94. So the intent shown to the user will be I don’t have any tremors which is incorrect. We have provided a report option next to the patient response, on clicking this icon a nearby list of predictions made by the language model are shown in a popup as shown in figure 8. When user clicks on Any Panadol taken? the response I haven’t taken any Panadol is shown to the user.

USER STUDY TO IMPROVE HISTORY TAKING

In phase 2 of the study, we focused mainly on thoroughly allowing the system to begin learning new questions that clinicians would often use. Ensuring the robustness of the system and allowing usage by people with different levels of medical experience. A total of 9 fourth year medical students were recruited to test the system. Students were instructed to be as thorough as they can be in this experiment. They were given instructions that they should cover only the interview portion, something learned in their second year and using it as a skeletal guideline in their “quest”. The viewing of the tutorial was done at the beginning after their consent was taken. Each participant was tasked to complete 4 cases thoroughly. There was an improvement in the performance of the model after incorporating the feedback of the usability study. A total of 2169 user interactions were performed while interviewing the patients. Of them, 1678 (77.4%) were correctly predicted, 71 (3.3 %) unknown concepts can be corrected using the error correction approach described above, 186 (8.6 %) were the unknown concepts not be able to correct using the error correction approach, and 234 (10 %) were out-of-domain concepts.

CONCLUSION AND FUTURE WORK

Medical students feel clinically unprepared after graduation due to lack of access to real patients. Virtual integrated patient allows the student to interact with the patient more naturally and realistically. The VIP generates virtual patients that students can use to rehearse and practice skills to engage a patient through the interview, examinations, and ordering of investigations. The primary interface is through free text. We have evaluated this tool with seven medical students and six clinicians (tutors). Each participant completed three questionnaires (user experience questionnaire, system usability scale, and a self-developed questionnaire). In all the surveys, there was a significant difference between the students’ and clinicians’ scores. We also noticed that around 30% of the questions asked were new to the platform, resulting to frustration in participants. We incorporated the usability study feedback and designed an error correction for unknown concepts, and found an improvement in the
performance of chatbot after engaging 9 new medical students to intensively test the history taking component of the website.

We believe that the VIP Interview chatbot can be further improved with increased participants interaction. We can use this tool to develop virtual populations of patients according to relevant demographics as well as even more complex patients with multiple clinical episodes, and clinical sequela necessitating follow-ups. We are building this platform to include more customisable features accommodating to the specific needs of different teaching environments, medical schools, and end-users.

ACKNOWLEDGEMENTS

We want to express our sincere gratitude to Professor Teo Boon See, Kong Shu Min Juanita, Lee Yueh Jia in helping to conduct the user study, to all the medical students, tutors signed up for the user study and to Mercy Steven who helped us in the generation of the patient database.
